Client overview

Aether is the suite layer for runtime portability, giving teams one declarative model that can target Podman, Kubernetes, KubeVirt, or bare metal without rewriting deployment intent.

Primary audience

Platform architects, DevOps leadership, hybrid infrastructure teams

- Use this when the client wants one deployment abstraction across containers, VMs, and bare metal.
- It is the control-plane story for hybrid runtime portability, not just a deployment utility.

Why Zyvor AI Labs

Platform-first infrastructure modernization without vendor lock-in.

Mission

Zyvor AI Labs builds HyperSDK Platform to make VM migration, lifecycle control, and infrastructure portability predictable, repeatable, and low risk.

- Open standards over proprietary lock-in: KVM, libvirt, and KubeVirt.
- Enterprise-first design with APIs, auditability, and operational discipline.
- A single suite spanning migration, operations, and infrastructure governance.

Why clients engage

Customers engage Zyvor when they need one operating narrative across migration, virtualization, platform operations, observability, and infrastructure modernization.

- VMware exit and cloud cost pressure need a real operating plan, not point tooling.
- Migration projects now have to connect directly to day-2 platform operations.
- Leadership teams want one portfolio story they can scale over time.

Where Aether fits in the portfolio

Each product solves an immediate problem, but gains more value when positioned inside the broader HyperSDK Platform story.

SUITE ALIGNMENT	WHAT THAT MEANS IN CLIENT TERMS
Fit 1	Connects migration tooling with the suite’s runtime and infrastructure products.
Fit 2	Pairs with IronWolf for bare-metal outcomes and with KubeVirt products for VM-based deployment paths.
Fit 3	Acts as a control-plane abstraction where the rest of the portfolio provides specialized runtime depth.

Aether

One declarative spec across containers, VMs, and bare metal.

Aether is the suite layer for runtime portability, giving teams one declarative model that can target Podman, Kubernetes, KubeVirt, or bare metal without rewriting deployment intent.

Call framing

- Use this when the client wants one deployment abstraction across containers, VMs, and bare metal.
- It is the control-plane story for hybrid runtime portability, not just a deployment utility.

Why it matters

- Reduces per-environment manifest drift.
- Lets teams promote workloads across different runtime boundaries.
- Creates a clearer operating model for hybrid infrastructure.

What it does well

- Single workload specification.
- Runtime portability across Podman, Kubernetes, KubeVirt, and bare metal.
- Multiple rollout and migration strategies.

Best-fit clients

- Hybrid platform teams.
- Organizations modernizing gradually across runtime types.
- Teams that want one application deployment narrative across environments.

Recommended follow-through

Use this deck to align stakeholders, then move quickly into a tailored technical session.

Recommended next moves

- Map one application journey from development to production across preferred runtimes.
- Follow with deployment architecture review and promotion workflow demo.

Discussion prompts

- What first-wave problem is Aether solving in the target environment?
- Which teams own the operational outcome after rollout?
- What proof point or demo would shorten the path from interest to design review?
